Synthetic Observational Cohort Beta: A Fabricated Example Document

Abstract

This is a synthetic observational cohort description produced by a test script. Nothing in it is real or citable.

It exists so that a retrieval system can be tested against more than one document and more than one study design.

Data Source and Cohort

The fabricated analysis used the Invented Regional Health Records Extract, a fictional dataset created solely for this test file.

The synthetic cohort comprised 15,204 imaginary records collected between the invented years 2015 and 2021. No real records, and no patient data of any kind, are represented here.

Fictional follow-up was recorded for a median of 3.8 invented years.

Biomarkers Considered

Three fabricated biomarkers were examined in this synthetic analysis: an invented inflammatory marker referred to as SYN-CRPx, a fictional metabolic marker referred to as SYN-GLYm, and a made-up genetic variant score referred to as SYN-VARs.

Fabricated measurement of these invented biomarkers was assumed to occur at baseline and at each fictional annual visit.

None of these biomarkers exist. They are placeholders that let a biomarker question be answered from a known page.

Statistical Analysis

The synthetic analysis plan describes fabricated Cox proportional hazards models adjusted for invented covariates including age, sex and a fictional deprivation index.

Missing values in this imaginary dataset were handled by fabricated multiple imputation with five invented imputations.

Limitations

The fabricated limitations of this synthetic cohort include its observational design, which in this fictional scenario prevents any causal claim; invented residual confounding; and made-up misclassification of the fictional exposure definition.

The authors of this synthetic document also note fabricated incompleteness in the invented records before the fictional year 2017.
